Seismic Design Factors. The following factors affect and are affected by the design of the building. It is important that the design team understands these factors and deal with them prudently in the design phase. Torsion: Objects and buildings have a center of mass, a point by which the object (building) can be balanced without rotation occurring.

However, when designing critical structures such as dams, high-rise buildings, etc. it is observed that a certain magnitude of peak ground acceleration (PGA) is considered. In this article, we are concentrating on the factors to be considered in seismic design from the preliminary stage to the completion of the design of the structure.

Seismic Design Principles - Factors to be Considered ...

Design of buildings to resist earthquakes involves controlling the damage to acceptable levels at a reasonable cost. Contrary to the common thinking that any crack in the building after an earthquake means the building is unsafe for habitation, engineers designing earthquake-resistant buildings recognize that some damage is unavoidable.

potential seismic risk as represented by the Seismic Design Category increases, the Provisions requires progressively more rigorous seismic design and construction as a means of attempting to ensure that all buildings provide an acceptable risk to the public. Thus, as the SDC for a structure increases, so do the strength and

This means the loss of life should be minimized by preventing collapse of the buildings. Seismic design is carried out by understanding the possible failure modes of a structure and providing the structure with appropriate strength, stiffness, ductility, and configuration to ensure those modes cannot occur.
